

ASSIGNMENT 1

MVC Design pattern-

MVC is a design pattern used to separate concerns in software architecture.

- Model - manages data and business logic
- View - Handles the display/presentation layer
- Controller - Processes user input and updates the model and view accordingly.

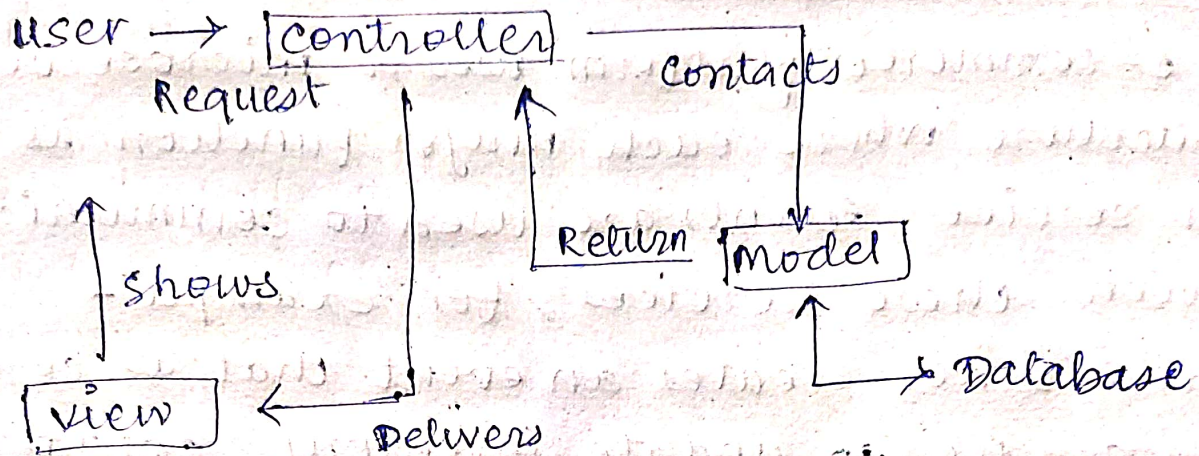

Model View controller pattern specifies that an application consists of a data model, presentation layer information and control information.

The pattern requires that each of these can be separated into different objects.

- the MVC pattern separates the concerns of an application into direct three distinct components, each responsible for a specific aspect of the application's functionality
- The separation of concern makes the application easier to maintain and to extend as changes to one component do not require changes to the other components.

MVC keeps everything organised and improves the quality of the software

Communication between the components -

- User Interaction with View
- View Receives user input
- Controller Processes user input
- Controller updates model
- Model notifies view of changes
- View Request Data from Model
- Controller updates View
- View Renders updated UI
